Algorithms for the problems that matter

Advanced Computational Algorithms provides a rigorous yet practical guide to the design, analysis, implementation, and evaluation of modern algorithms.

The Second Edition develops mathematical foundations while connecting theory to executable implementations and real-world computational problems. Topics include asymptotic analysis, divide-and-conquer methods, advanced data structures, greedy and dynamic programming techniques, randomized and approximation algorithms, computational complexity and NP-completeness, graph algorithms, string processing, numerical methods, and modern algorithm engineering.

Worked examples, pseudocode, executable code, instructional diagrams, proofs, exercises, benchmarking activities, and applied projects help readers move from understanding algorithms to evaluating how they behave in practice.

Designed for advanced undergraduate and graduate students, instructors, software engineers, data scientists, researchers, and technical professionals, the book emphasizes correctness, complexity, performance evaluation, reproducibility, and computational problem solving.

ABOUT THE AUTHOR

Moody Amakobe is a multidisciplinary researcher, data scientist, and blockchain architect whose work spans artificial intelligence, computational systems, data engineering, and distributed architectures. As founder of the Global Data Science Institute, he leads work in data science, deep learning, algorithm design, and technology for impact. He has taught at multiple universities, authored technology textbooks, advised research teams, supervised graduate projects, and developed industry solutions across healthcare, finance, agriculture, and public systems.
